Abstract

The epicardium plays an important role in coronary vessel formation and *Tgfb β 3*^{-/-} mice exhibit failed coronary vessel development associated with decreased epicardial cell invasion. Immortalized *Tgfb β 3*^{-/-} epicardial cells display the same defects. *Tgfb β 3*^{+/+} and *Tgfb β 3*^{-/-} cells incubated for 72 hours with VEH or ligands known to promote invasion via TGF β R3 (TGF β 1, TGF β 2, BMP2), for 72 hours were harvested for RNA-seq analysis. We selected for genes >2-fold differentially expressed between *Tgfb β 3*^{+/+} and *Tgfb β 3*^{-/-} cells when incubated with VEH (604), TGF β 1 (515), TGF β 2 (553), or BMP2 (632). Gene Ontology (GO) analysis of these genes identified dysregulated biological processes consistent with the defects observed in *Tgfb β 3*^{-/-} cells, including those associated with extracellular matrix interaction. GO and Gene Regulatory Network (GRN) analysis identified distinct expression profiles between TGF β 1-TGF β 2 and VEH-BMP2 incubated cells, consistent with the differential response of epicardial cells to these ligands *in vitro*. Despite the differences observed between *Tgfb β 3*^{+/+} and *Tgfb β 3*^{-/-} cells after TGF β and BMP ligand addition, GRNs constructed from these gene lists identified NF- κ B as a key nodal point for all ligands examined. *Tgfb β 3*^{-/-} cells exhibited decreased expression of genes known to be activated by NF- κ B signaling. NF- κ B activity was stimulated in *Tgfb β 3*^{+/+} epicardial cells after TGF β 2 or BMP2 incubation, while *Tgfb β 3*^{-/-} cells failed to activate NF- κ B in response to these ligands. *Tgfb β 3*^{+/+} epicardial cells incubated with an inhibitor of NF- κ B signaling no longer invaded into a collagen gel in response to TGF β 2 or BMP2. These data suggest that NF- κ B signaling is dysregulated in *Tgfb β 3*^{-/-} epicardial cells and that NF- κ B signaling is required for epicardial cell invasion *in vitro*. Our approach successfully identified a signaling pathway important in epicardial cell behavior downstream of TGF β R3. Overall, the genes and

signaling pathways identified through our analysis yield the first comprehensive list of candidate genes whose expression is dependent on TGF β R3 signaling.

Introduction

The epicardium plays an important role in coronary vessel development (reviewed [1–3]). Formation of the epicardium occurs when a population of mesothelial cells, termed the proepicardium, attach to and migrate over the heart tube myocardium [4, 5]. Subsequently, a subpopulation of the epithelial, epicardial cells lose epithelial character, change shape, and invade the underlying matrix in a process termed epithelial-mesenchymal transformation (EMT). The resulting mesenchymal cells invade into the subepicardial space with some cells proceeding to invade into the myocardium as well (reviewed [6]). These epicardial-derived cells differentiate into distinct lineages [7–11], that include cardiac fibroblasts, pericytes, and vascular smooth muscle cells, and support the formation of coronary vessels. Several reports support epicardial contribution to the coronary endothelial cell lineage [12–14]. Numerous lines of evidence are now revealing the importance of these same developmental processes in cardiac repair and that the epicardium makes critical contributions to cardiac response to injury (reviewed [6]). Despite this, the signaling processes which regulate epicardial EMT are incompletely understood.

TGF β R3 deletion in mice leads to failed coronary vessel development [15]. *Tgfb β 3*^{−/−} hearts featured a discontinuous epicardium overlying an expanded subepicardial space. Further studies revealed a significant decrease in proliferation and invasion of epicardium and epicardially-derived mesenchyme [16]. Overall, these studies demonstrated that TGF β R3 plays an important and non-redundant role in epicardial behavior and coronary vessel development *in vivo*.

TGF β R3 binds TGF β 1, TGF β 2 and TGF β 3 and is uniquely required to bind TGF β 2 with high affinity [17, 18]. TGF β R3 is also capable of binding and signaling in response to BMP2 [19] and functions as a receptor for inhibin [20]. TGF β R3 presents ligand to TGF β R2 to promote both Smad-dependent and -independent signaling [21]. The highly conserved 43 amino acid intracellular domain of TGF β R3 is not required for ligand presentation [22] but may regulate other signaling events. Phosphorylation of the cytoplasmic domain of TGF β R3 by TGF β R2 at Thr841 is required for β -arrestin2 binding, leading to internalization of TGF β R3 and down-regulation of TGF β signaling. The 3 C-terminal amino acids of TGF β R3, STA, are a Class I PDZ binding domain that binds the scaffolding protein GIPC which in turn stabilizes TGF β R3 on the plasma membrane to promote signaling [23].

Tgfb β 3^{+/+} epicardial cells undergo loss of epithelial character and invasion into collagen gels *in vitro* in response to TGF β 1, TGF β 2, and BMP2, ligands known to bind TGF β R3 [18, 24]. While loss of epithelial character was still observed after loss of TGF β R3, *Tgfb β 3*^{−/−} cells had reduced invasion in response TGF β 1, TGF β 2, and BMP2, a response that was rescued by the addition of TGF β R3 [16, 25, 26]. TGF β 1 and TGF β 2 promoted smooth muscle differentiation in *Tgfb β 3*^{+/+} and *Tgfb β 3*^{−/−} cells while BMP2 did not [26]. Surprisingly, other ligands known to be important in epicardial EMT also required TGF β R3 to promote invasion in epicardial cells (FGF2 [27, 28], High Molecular Weight HMW-HA [29, 30]). Impaired invasion of three-dimensional gels by epicardial-derived mesenchyme was not due to the permanent loss of invasive properties, as PDGFAA, PDGFBB and VEGFC still induced invasion in *Tgfb β 3*^{−/−} epicardial cells [16].

This ability of TGF β R3 to regulate epicardial cell behavior in response to an array of ligands may explain the severity of the *in vivo* phenotype of *Tgfb β 3*^{−/−} embryos when compared to the absence of a phenotype in mice lacking individual TGF β ligands [31–33]. It is known that the

loss of cell invasion has effects on cardiovascular development outside of the loss of the direct contributions of these cells to the structure of the coronary vessels. The deletion of several genes, encoding proteins that perform an array of functions including transcription factors, adhesion molecules, and growth factor ligands or receptors, share a common phenotype of a thinned myocardium (reviewed in [3]). These data as well as experimental embryology experiments in avian embryos have been interpreted to demonstrate that epicardially-derived mesenchymal cells are necessary for growth of the compact zone of the myocardium (reviewed in [34]). Therefore, the formation of the epicardium and the resultant generation of mesenchyme is critical for the support of both coronary vessel formation and myocardial growth. For example, targeted deletion of ALK5 in the epicardium in mice *in vivo* results in interrupted epicardial attachment to the myocardium, loss of expression of specific adhesion molecules, thinned myocardium, and a loss of coronary smooth muscle [33]. These embryos survive until birth, suggesting that, unlike in embryos lacking TGF β R3, the coronary vessels function to some degree as mice lacking coronary vessels die at approximately E14.5-E16.5 [35–37]. These data suggest that TGF β R3 signaling regulates a common pathway accessed by several upstream regulators of cell invasion.

TGF β R3-dependent invasion stimulated by TGF β 1, TGF β 2, BMP2, HMW-HA, or FGF2 was shown to require the cytoplasmic domain of TGF β R3 *in vitro* [16]. Overexpression of TGF β R3 rescued invasion in *Tgfb3*^{-/-} epicardial cells *in vitro* in response to TGF β 1, TGF β 2, BMP2, HMW-HA, or FGF2, whereas constructs expressing a TGF β R3 mutant lacking the 3 C-terminal amino acids required for GIPC binding fail to rescue invasion [16, 25, 26]. The importance of this interaction is further supported by the observation that GIPC is not only required for invasion in *Tgfb3*^{+/+} epicardial cells, but GIPC overexpression can promote invasion in the absence of additional ligand. GIPC regulation of epicardial invasion depends on TGF β R3 since GIPC expression in *Tgfb3*^{-/-} cells fails to rescue invasion and inhibition of GIPC expression impairs the ability of TGF β R3 to rescue invasion in *Tgfb3*^{-/-} cells [16]. Similar results were observed in endocardial cushions where the interaction of TGF β R3 with GIPC is required to promote TGF β 2- and BMP2-dependent invasion *in vitro* [38]. These data linking defects in invasion of *Tgfb3*^{-/-} epicardial cells to the cytoplasmic domain of TGF β R3, which is not required for ligand presentation, suggests a unique, non-redundant role for TGF β R3 in regulating epicardial and endocardial EMT.

Here, we use a well defined *in vitro* system based on immortalized epicardial cells coupled with RNA-seq analysis to generate a transcriptional profile of *Tgfb3*^{+/+} and *Tgfb3*^{-/-} cells incubated with ligands that stimulate TGF β R3-dependent invasion. The resulting transcriptional profiles have identified regulators of epicardial cell behavior downstream of TGF β R3 and provided the first description of genes downstream of TGF β R3.

Methods

Generation of cell lines

Tgfb3^{+/+}:Immorto mice were generated as described [39] and maintained on a C57BL/6 SV129 mixed background. *Tgfb3*^{+/+}:Immorto and *Tgfb3*^{-/-}:Immorto immortalized epicardial cell lines were generated from littermates as described [39] from E11.5 embryos (Fig 1A and 1B). The original work that covered the generation of the embryonic epicardial cell lines used in these studies was carried out as approved on protocol M/13/156 (Joey Barnett, PI) by the Institutional Animal Care and Use Committee of Vanderbilt University.

Cell culture

To maintain the immortalized state, cells were grown at 33°C in DMEM containing 10% fetal bovine serum, 100 U/ml penicillin/streptomycin, Insulin–Transferrin–Selenium (ITS: 1 µg/ml

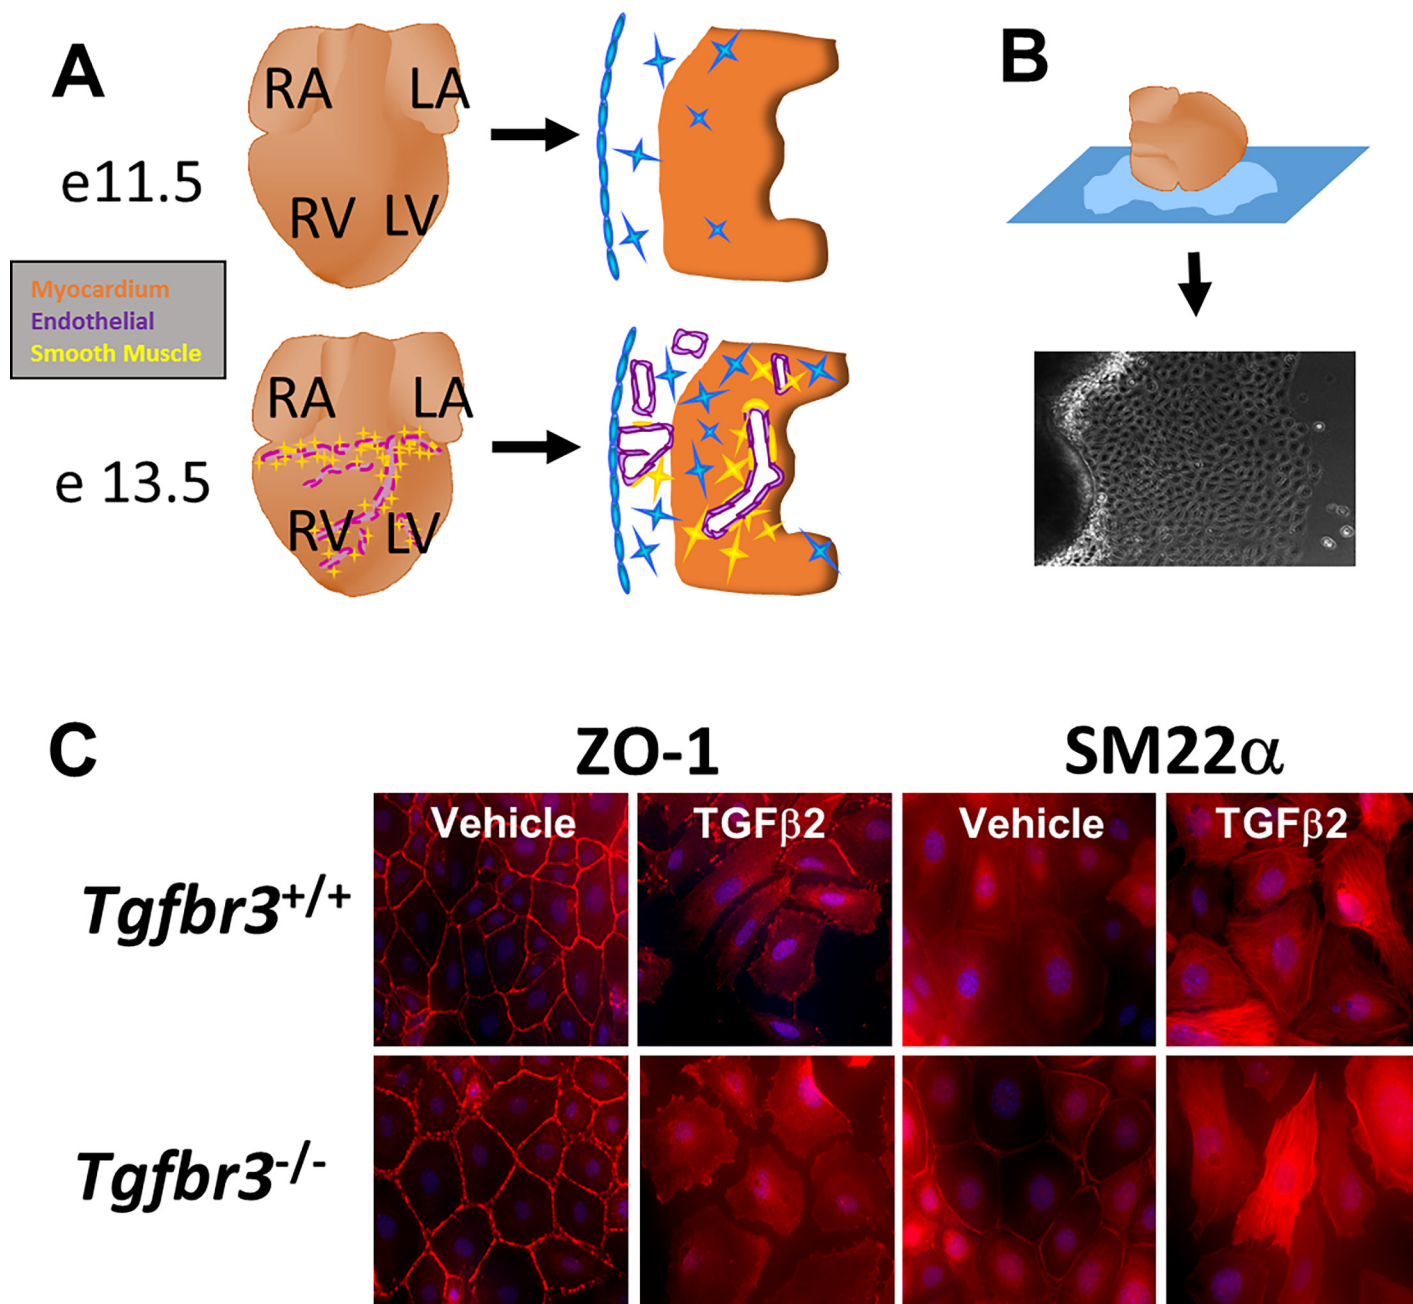

Fig 1. Immortalized epicardial cells undergo loss of epithelial character. (A) The epicardium undergoes EMT at E11.5–13.5. Subsequently, transforming epicardial cells invade the subepicardial space and myocardium towards forming coronary vessels. Blue- epicardium. Purple- endothelium. Yellow- smooth muscle cells. Red- myocardium. (B) Immortalized epicardial cells were derived from E11.5 *Tgfbr3*^{+/+} and *Tgfbr3*^{-/-} embryos which expressed a temperature-sensitive large T-antigen. doi:10.1371/journal.pone.0159710.g001

insulin, 5.5×10^{-4} μ g/ml transferrin, 0.677 μ g/ml selenium), and 10 U/ml interferon γ (INF γ). For experiments, the T-antigen was inactivated by culturing at 37°C in the absence of ITS or INF γ . Cells were seeded at 200,000 cells per well of a 6-well tissue culture plate and allowed to adhere overnight at 37°C. The following day the medium was replaced with media containing

either VEH, 250 pM TGF β 1, 250 pM TGF β 2, or 5 nM BMP2. After a 72 hour incubation period at 37°C, total RNA was isolated via standard phenol-chloroform extraction (TRIzol Invitrogen). RNA was purified (Qiagen mini-prep kit) following the manufacturer's protocol. Quantity and quality of RNA was determined by an Agilent Bioanalyzer. One well of a 6-well plate yielded 10–20 μ g of RNA.

qRT-PCR

Quantitative Real Time PCR qRT-PCR was performed as described [16]. Briefly, cDNA was generated from 1 μ g total RNA using oligo-dT primers and Superscript III polymerase (Invitrogen). Real-time PCR analysis was done with iQ SYBR Green Supermix (Bio-Rad) in the Bio-Rad iCycler for 40 cycles. Primer pairs forward (F) and reverse (R): *GAPDH* F-ATGACAATGAATACGGCTACAG, R-TCTCTTGCTCAGTGTCCTTG; *Mylk* F-CCAAGGACCGGATGAAGAAATA, R-CCCTGAGATCATTGCCATAGAG; *Sema3d* F-TGGGACATAGAAGCATTAG, R-AGAGGCTTGTTGGGATTAGG; *Sxc* F-AGGGCCTATGAACAGAGAGAT, R-GTAGAGAGCCAGCATGGAAAG; *Cadm1* F-TCTGTAGGCGGCTCAGTATAG, R-CTCACATGTCGGGTCTGTTTAG; *Krt8* F-GGCCAACCTTAGGAGGAATTT, R-GAGCCAGCTGAGGCTTTATT; *Chst7* F-GTGAGACACTGGGACTGATTTG, R-GCCAAGGTGTCTGTTCATTA CTT; *Versican* F-CAGGCTATCACAGGCAGATTAG, R-CAGAAGCCAAGGAGTCATTCA.

RNA-seq

The generation of RNAseq libraries without normalizations or RNA/cDNA fragmentation were performed as described [40]. Libraries were sequenced as 50bp paired end sequences on a single lane of the Illumina HiSeq2000. TOPHAT [41] (<http://tophat.cbcb.umd.edu/>) was used to align HiSeq 2000 reads to produce bam files. Reads were normalized to total mRNA (total aligned reads per gene-loci per million). Gene expression profiles were generated as described [42] using a Bayesian p-value (S1 and S2 Figs). Data deposited at the Cardiovascular Development Consortium (CvDC) Data Repository (<https://hci-bio-app.hci.utah.edu/gnomex/>), external experiment number 38R1 (<https://b2b.hci.utah.edu/gnomex/gnomexGuestFlex.jsp?requestNumber=38R1>).

SEAP Reporter System

The pNF- κ B-SEAP (Clontech) reporter was used to determine NF- κ B activity in cells as described [43, 44]. Briefly, cells were co-transfected with pNF- κ B-SEAP and β -galactosidase expression vector (p-CMV β) and after 24 hours incubated with ligand (250pM TGF β 1, 250 pM TGF β 2, or 5nM BMP2). 24 hours after ligand addition the supernatant was assayed for alkaline phosphatase. β -galactosidase activity was used to normalize alkaline phosphatase activity.

Transwell Invasion Assay

Invasion assay performed using a collagen pad in a transwell as described in [16].

Results

Transcriptional profiles of *Tgfr3*^{+/+} and *Tgfr3*^{-/-} cells confirm epicardial cell identity and ligand response

We undertook a transcriptional profiling approach to examine the genes downstream of TGF β R3 in epicardial cells *in vitro*. This system was chosen since it provides defined phenotypic endpoints to contrast between genotypes and different ligand incubation groups (Fig 2A).

doi:10.1371/journal.pone.0159710.g002

Tgfr3^{+/+} and *Tgfr3^{-/-}* epicardial cells were incubated for 72 hours with VEH or ligands known to drive TGFβR3-dependent invasion (TGFβ1, TGFβ2, BMP2) [25]. After incubation RNA was harvested and analyzed by RNA-seq as described. More than 24 million reads were obtained for each group (VEH, TGFβ1, TGFβ2, BMP2) in each genotype (Fig 2B—Genes). Over 13,900 genes were significantly expressed (Reads >10) in each dataset (Fig 2B—Reads). Of these genes, we observed that markers of embryonic epicardial cells (*Wt1* [45], *Tbx18* [46], *Sema3d* [14], *Scx* [14]) were expressed in all data sets (Fig 3A) but markers of endothelial (*Cdh5* [47], *Pecam1* [48], *Tie1* [49]) or myocardial (*Tnni2* [50, 51], *Tnni3* [51, 52]) lineages were not (Fig 3). *Sema3a* and *Scx* expression were confirmed with qRT-PCR (S3 Fig). The expression profile observed confirms the epicardial identity of these cells.

We have previously reported that TGFβ1 and TGFβ2 promote loss of epithelial character, invasion, and smooth muscle differentiation defined as the increased expression of the smooth muscle markers *α-Sma*, *Sm22α*, and *Cnn1* (reviewed [53]) in *Tgfr3^{+/+}* and *Tgfr3^{-/-}* epicardial cells (TGFβ2 depicted in Fig 1C). BMP2 promotes loss of epithelial character and invasion but not smooth muscle differentiation [26]. RNA-seq data sets demonstrated that the level of expression of *α-Sma*, *Sm22α*, and *Cnn1* were >2-fold higher in TGFβ1- and TGFβ2-incubated cells of each genotype (Fig 3B). BMP2 incubation resulted in a considerably lower induction of smooth muscle markers (Fig 3B). Hundreds of genes had >2-fold increased or decreased expression after TGFβ1 or TGFβ2 incubation (Fig 3B). Far fewer genes were >2-fold differentially expressed after BMP2 incubation (Fig 3B) which may be at least partially due to the inability of BMP2 to induce smooth muscle differentiation. Of note, fewer genes were induced with TGFβ1 or TGFβ2 incubation in *Tgfr3^{-/-}* cells when compared to *Tgfr3^{+/+}* cells, while the opposite was found with BMP2 incubation. This transcriptional profile of *Tgfr3^{+/+}* and

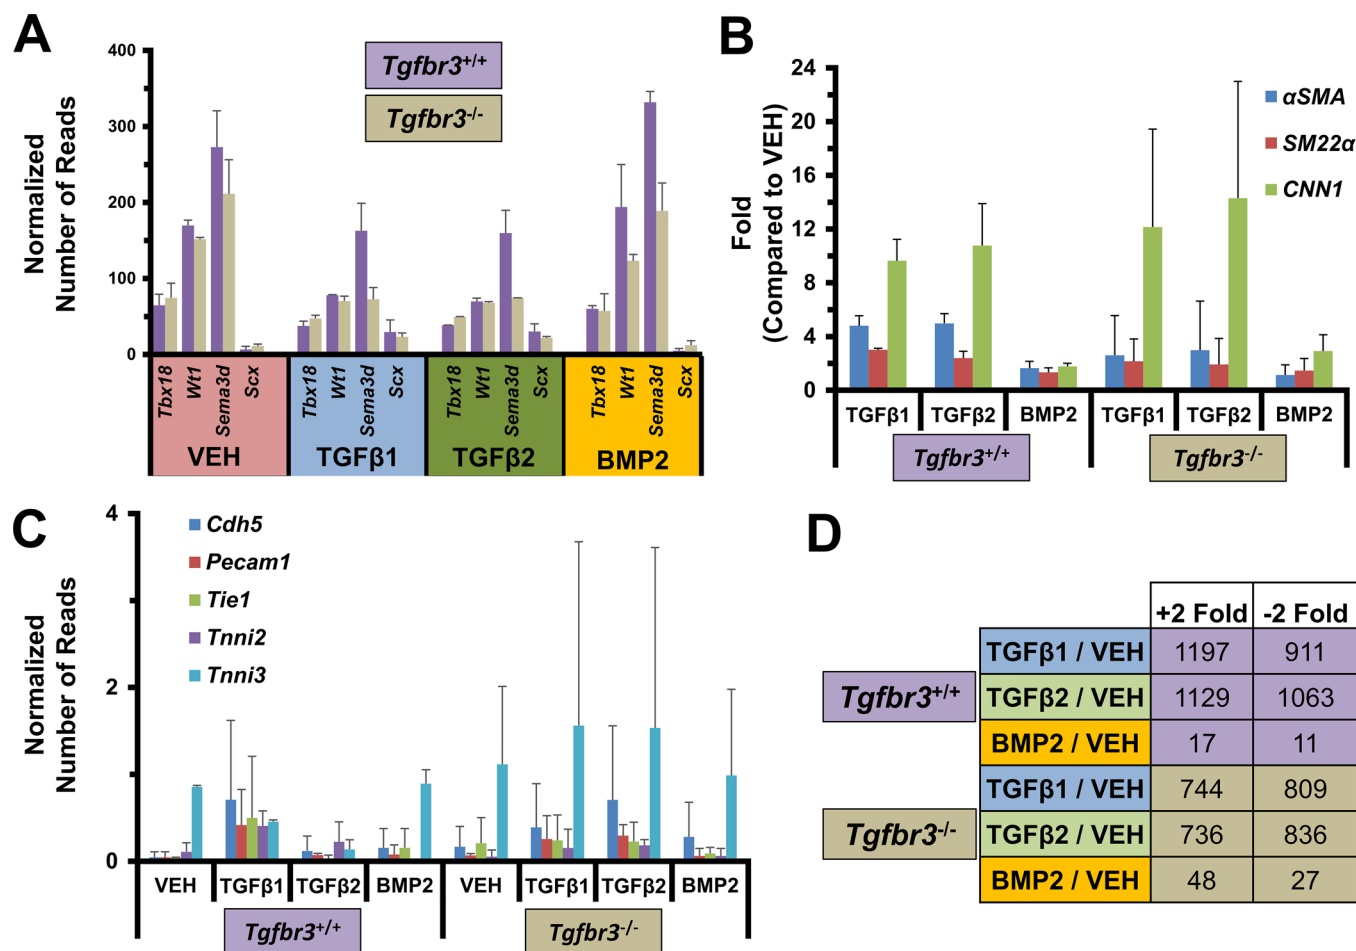

Fig 3. *Tgfr3*^{+/+} and *Tgfr3*^{-/-} epicardial RNA-seq datasets confirm cell identity and differential ligand response. (A) Cells express epicardial markers. Mean normalized reads between replicates and standard error are depicted. (B) Smooth muscle markers are markedly induced with TGF β 1 and TGF β 2 compared to BMP2 incubation. Fold is relative to VEH for each genotype. (C) Endothelial or myocardial markers are not expressed at significant levels (< 2 normalized reads). Mean normalized reads between replicates and standard error are depicted. (D) Genes >2-fold differentially expressed after ligand treatment compared to vehicle are depicted. Fewer genes are induced by incubation with TGF β 1–2 treatment in *Tgfr3*^{-/-} epicardial cells compared to *Tgfr3*^{+/+}, while the opposite is true with BMP incubation.

doi:10.1371/journal.pone.0159710.g003

Tgfr3^{-/-} epicardial cells confirms both the epicardial identity and the known response of these cells to ligand. Therefore, we used these data sets for further analysis towards delineating the downstream signaling pathways of TGF β R3 in the epicardium.

Dysregulation of gene expression in epicardial cells lacking TGF β R3

To ascertain the genes differentially regulated after the loss of *Tgfr3*, we compared the expression profiles of *Tgfr3*^{+/+} and *Tgfr3*^{-/-} epicardial cells incubated with VEH, TGF β 1, TGF β 2, or BMP2. We observed hundreds of genes >2-fold ($p < 0.001$) differentially regulated between genotypes in cells incubated with VEH (604), TGF β 1 (515), TGF β 2 (553), or BMP2 (632) (Fig 4A; S1–S4 Tables). The overlap between these >2-fold differentially expressed gene lists were plotted (Fig 4B) identifying 129 genes similarly dysregulated across all groups. This list of genes is defined as those that are differentially expressed after the loss of *Tgfr3* regardless of ligand incubation. To gain a better understanding of the biological processes these genes may be associated with, Gene Ontology (GO) analysis was undertaken using Database for

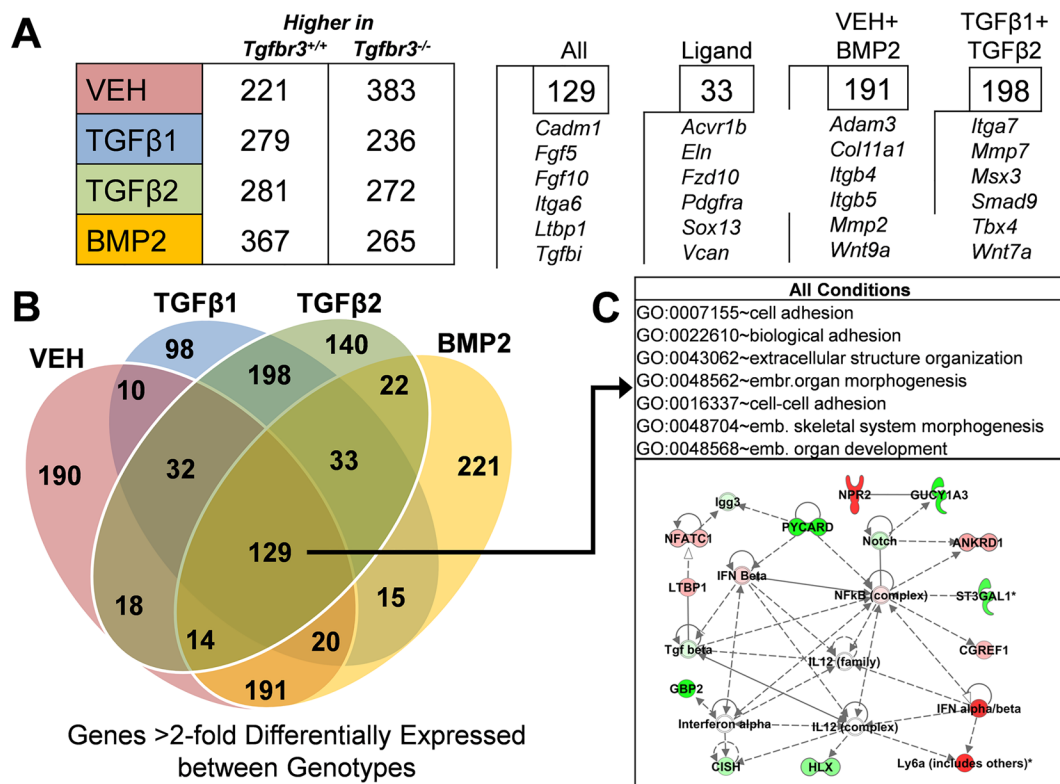

Fig 4. RNA-seq analysis identifies genes dysregulated in *Tgfr3*^{-/-} epicardial cells. (A) (Left) The number of genes >2-fold ($p < 0.001$) differentially expressed between *Tgfr3*^{+/+} and *Tgfr3*^{-/-} epicardial cells for each group. (Right) The number genes similarly dysregulated within selected groups that were also annotated in the IPA database are shown with genes found in each. (B) The number of overlapping genes >2-fold differentially regulated ($p < 0.001$) was determined and mapped. 129 genes were similarly dysregulated across all groups. (C) (Top) Gene ontology analysis of these 129 genes by DAVID revealed a significant ($p < 0.0001$) enrichment of genes associated with specific biological processes. emb.- embryonic. (Bottom) A representative network generated by gene regulatory network analysis of the 129 genes using Ingenuity Pathway Analysis software is depicted. Green-expressed higher in *Tgfr3*^{+/+}, Red- expressed higher in *Tgfr3*^{-/-}.

doi:10.1371/journal.pone.0159710.g004

Annotation, Visualization, & Integrated Discovery (DAVID) software [54]. GO analysis identified enriched biological processes ($p < 0.0001$) associated with cell adhesion and extracellular structure organization indicating a potential defect in cell interaction with the ECM, a vital component of cell invasion (Fig 4C–Top). In order to understand how these genes may interact, Ingenuity Pathway Analysis (IPA) software (www.ingenuity.com) was used to perform Gene Regulatory Network (GRN) analysis. An example network is depicted (Fig 4C–Bottom) which revealed TGFβ and Notch signaling pathways [55], both known important regulators of epicardial cell behavior and subsequent coronary vessel development. We also identified signaling pathways previously unexamined in epicardial development. For example, NF-κB signaling emerged as a central node in this analysis providing a candidate for further evaluation.

To gain a more detailed understanding of the genes dysregulated after loss of TGFβR3, we examined genes with dysregulated expression in specific ligand incubation groups. When considering the overlap between genes in at least any two groups (VEH, TGFβ1, TGFβ2, or BMP2) that are similarly >2-fold differentially expressed between genotypes (Fig 4B), we observed that there are many more genes shared between TGFβ1-TGFβ2 (198) and VEH-BMP2 (191) than any other comparison (for example; VEH-TGFβ1 (10), BMP2-TGFβ2 (22)). This may reflect the fact that both TGFβ1 and TGFβ2 induce smooth muscle differentiation. GO analysis

of the 198 genes uniquely dysregulated in *Tgfr3*^{-/-} cells after TGFβ1 and TGFβ2 incubation identified vasculature development as the most enriched biological process (p<0.001) (Table 1). This analysis is consistent with altered vascular development in the epicardium after loss of *Tgfr3*. However, processes associated with vascular development were not found to be significantly enriched by GO analysis in the 191 genes uniquely >2-fold dysregulated between genotypes with VEH and BMP2 incubation or in the 221 genes uniquely dysregulated with BMP2 incubation (Table 1).

Although we have reported that TGFβ2 promotes loss of epithelial character and smooth muscle differentiation via ALK5 signaling and BMP2 promotes only the loss of epithelial character via ALK3 signaling, both ligands require TGFβR3 to mediate invasion [26]. To gain a better understanding of how TGFβ and BMP signaling are impacted by the loss of *Tgfr3*, we examined genes >2-fold differentially expressed between *Tgfr3*^{+/+} and *Tgfr3*^{-/-} epicardial cells incubated with TGFβ2 or BMP2. GO analysis identified that biological processes associated with blood vessel development and angiogenesis were enriched (p<0.0001) in TGFβ2 but not BMP2 gene lists (genes including *Fgf2* and *Vegf*) (Fig 5A). Thus, while TGFβ induces smooth muscle differentiation in *Tgfr3*^{-/-} cells, there remain defects in the signaling networks associated with formation of the vasculature. Biological processes enriched in both of these TGFβ2 and BMP2 gene lists include processes associated with cell adhesion, extracellular matrix (ECM) organization, and proliferation (Fig 5A and 5B). These results are consistent with the known epicardial phenotype of *Tgfr3*^{-/-} embryos [15, 16].

To reveal interactions, genes >2-fold differentially expressed between genotypes after TGFβ2 or BMP2 incubation were used to generate GRNs using IPA software. Example networks are depicted in Fig 5C and 5D. The TGFβ2 network features predicted proteins known to be located in the ECM that regulate cell-ECM interactions. Several of these genes have lower levels of expression in *Tgfr3*^{-/-} cells compared to *Tgfr3*^{+/+} cells (green nodes). Also present are several genes encoding cytoplasm and plasma membrane proteins that are expressed at higher levels in *Tgfr3*^{-/-} epicardial cells compared to *Tgfr3*^{+/+} cells (red nodes). These genes

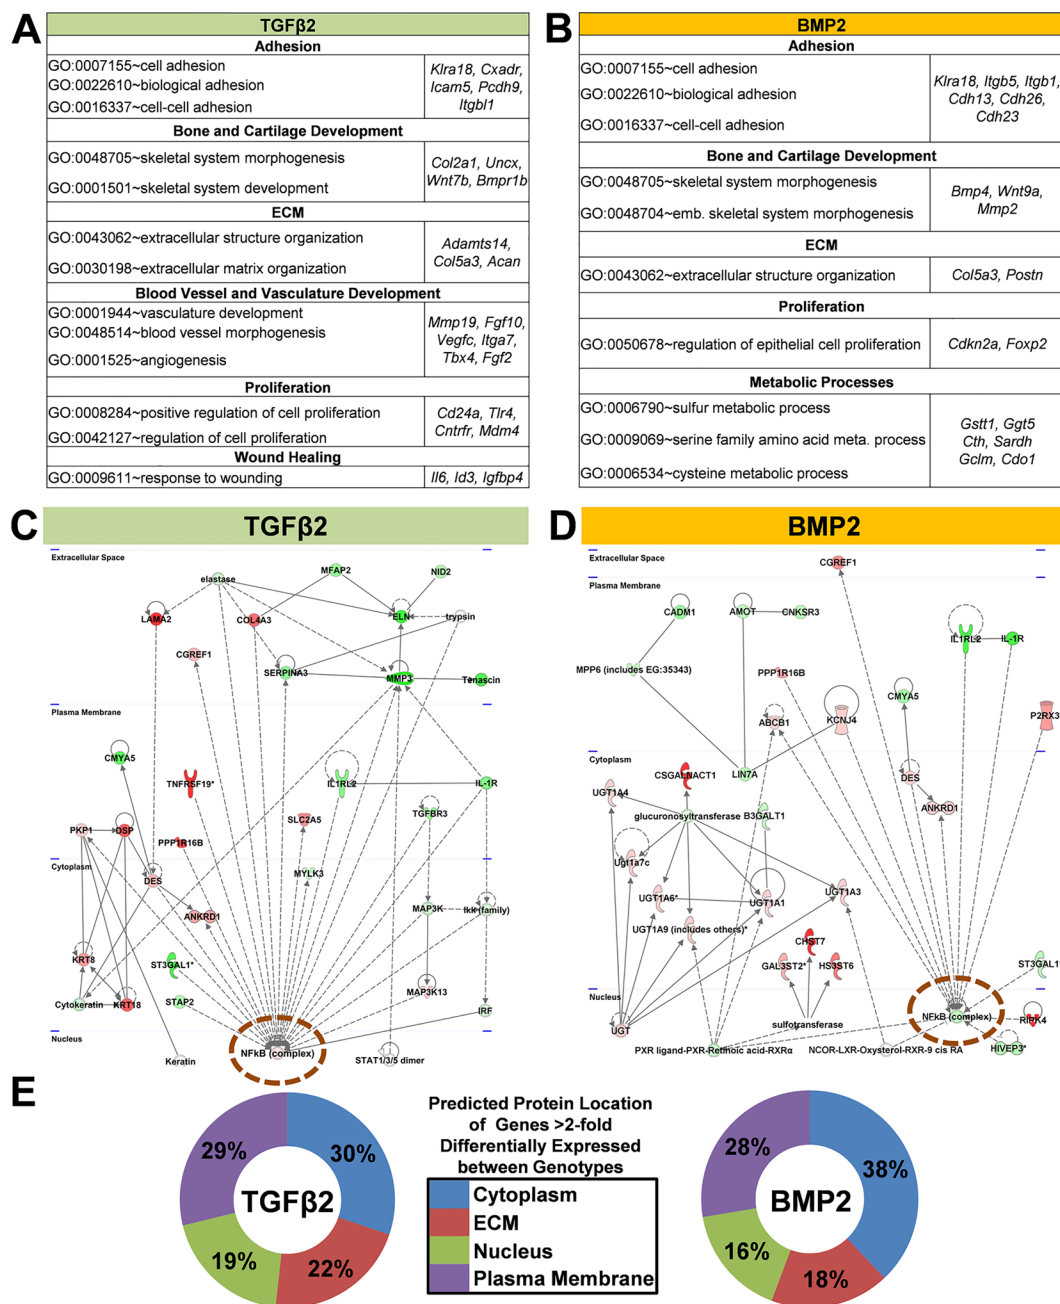

Fig 5. Gene regulatory network analysis identifies NF-κB signaling as a central node. Genes >2-fold ($p < 0.001$) differentially expressed between *Tgfb3*^{+/+} and *Tgfb3*^{-/-} epicardial cells incubated with either TGFβ2 (A) or BMP2 (B) were subjected to gene ontology analysis (using DAVID software, $p < 0.0001$). (C-D) NF-κB signaling (orange circle) is a central node in representative networks generated by gene regulatory network analysis (using Ingenuity Pathway Analysis software). Green- expressed higher in *Tgfb3*^{+/+}, Red- expressed higher in *Tgfb3*^{-/-}. (E) The distribution of the predicted protein location in the cell is depicted (proteins with unknown location are not shown).

doi:10.1371/journal.pone.0159710.g005

are associated with epithelial sheet stability and adhesion, for example *Krt18* and *Krt8*, whose expression pattern was confirmed using qRT-PCR (S3 Fig). The BMP2 network also features genes that are expressed at higher levels in *Tgfb3*^{+/+} cells whose proteins are known to associate with the plasma membrane to regulate cell adhesion and cell migration (*Lin7a* [56], *Amot*

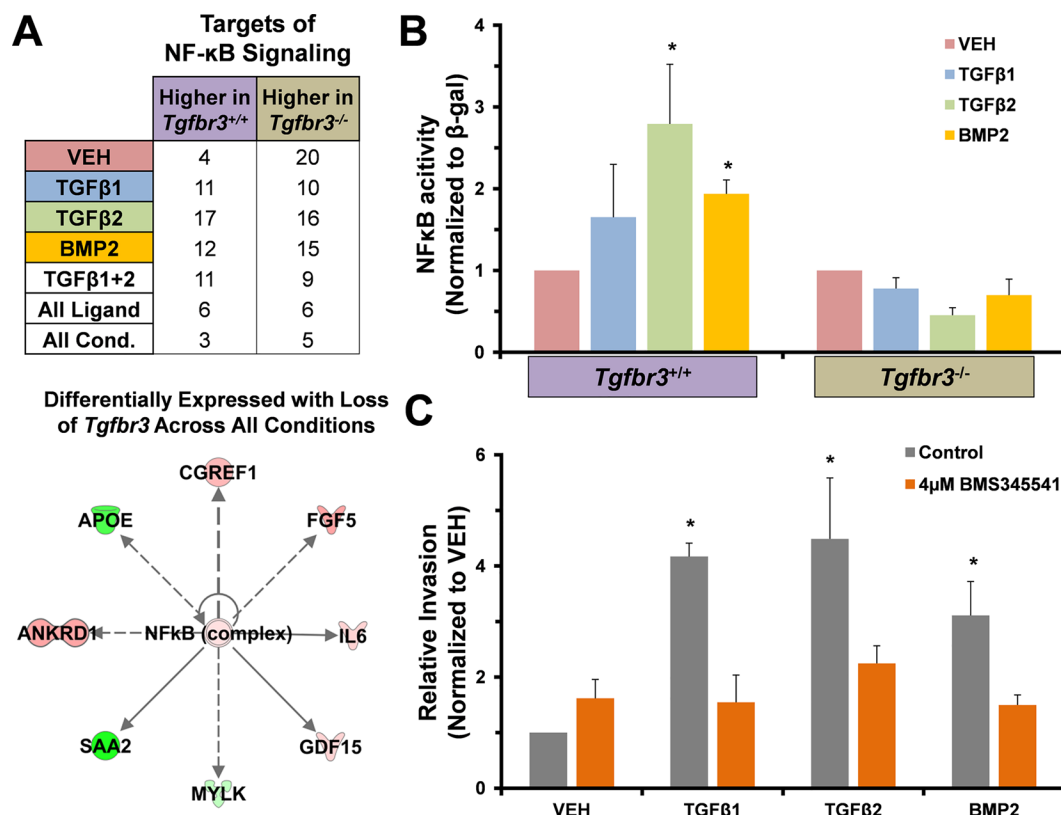

Fig 6. *Tgfr3*^{-/-} epicardial cells fail to activate the NF-κB signaling pathway. (A) (TOP) Genes dysregulated in each group (>2-fold, $p < 0.001$) were counted. (BOTTOM) Shared targets of NF-κB signaling dysregulated in all groups are shown. Red—expressed higher in *Tgfr3*^{+/+}, Green—expressed higher in *Tgfr3*^{-/-}. (B) Cells transfected with an NF-κB responsive SEAP reporter construct and incubated with VEH, TGFβ1, TGFβ2, or BMP2 revealed the inability of *Tgfr3*^{-/-} cells to induce NF-κB signaling. (C) Incubation of *Tgfr3*^{+/+} epicardial cells in a transwell invasion assay with an NF-κB inhibitor (BMS345541) significantly reduced invasion ($* = p < .01$) in response to ligands known to promote *Tgfr3*-dependent invasion.

doi:10.1371/journal.pone.0159710.g006

[57]). Nodes associated with ECM protein synthesis (*Csgalnact1* [58]) or post translation modification of receptors that interact with ECM (*Chst7* [59]) were also observed in the BMP2 network and the induction of *Chst7* in immortalized epicardial cell was confirmed using qRT-PCR (S3 Fig). These networks indicate a deficit in the ability of cells to interact with the ECM and a potential defect in cell motility. NF-κB was a central node in not only the TGFβ2 and BMP2 networks (Fig 5C and 5D—Orange circle), but also in GRNs derived from genes differentially expressed between genotypes with VEH or TGFβ1 incubation (S4 Fig). We identified several genes known to be downstream of NF-κB signaling that were differentially regulated in each ligand incubation group (S5A–S5D Fig) when compared between genotypes. A table depicting the overlap between these genes is shown (Fig 6A–Top). GRN analysis indicates that NF-κB signaling may be dysregulated with loss of TGFβR3 in epicardial cells. The dysregulated NF-κB signaling in both TGFβ2 and BMP2 gene lists, where a common phenotype is loss of invasion, suggests that NF-κB signaling may regulate cell invasion in response to these ligands.

NF-κB signaling is dysregulated in *Tgfr3*^{-/-} epicardial cells *in vitro*

To test the hypothesis that TGFβR3 promotes NF-κB signaling to regulate epicardial cell invasion we examined if NF-κB activity was induced by TGFβ2 or BMP2 ligand incubation in

epicardial cells *in vitro* (Fig 6B). Immortalized epicardial cells incubated with TGF β 2 or BMP2 increased NF- κ B activity compared to VEH in *Tgfr3*^{+/+} epicardial cells as described [44]. TGF β 2 or BMP2 ligand incubation failed to induce NF- κ B activity in *Tgfr3*^{-/-} cells (Fig 6B). To determine if NF- κ B signaling was required for epicardial cell invasion *in vitro*, we performed a collagen pad, transwell invasion assay with TGF β 1, TGF β 2, and BMP2 in the presence or absence of the NF- κ B inhibitor, BMS345541. BMS345541 (10 μ m) significantly decreased TGF β 1-, TGF β 2-, or BMP2-induced invasion in *Tgfr3*^{+/+} cells when compared to VEH (Fig 6C). Together these data demonstrate that NF- κ B signaling is dysregulated in *Tgfr3*^{-/-} epicardial cells and that NF- κ B is required for epicardial cell invasion *in vitro*. These data support the hypothesis that TGF β R3 promotes NF- κ B activity to regulate epicardial cell invasion.

Discussion

Transcriptional profiling of epicardial cells

We developed a transcriptional profiling strategy using immortalized, embryonic epicardial cells *in vitro* to identify genes and signaling pathways downstream of TGF β R3 that regulate cell invasion. Previous studies have profiled gene expression in adult epicardial cells [60, 61], the proepicardium [62], and primary epicardial cells (E12.5) [63] using microarrays, but a comprehensive transcriptional profiling of embryonic epicardial cells has been lacking. Additionally, our choice of this system allows for a first systematic examination of the genes and signaling pathways regulated by TGF β R3.

Tgfr3^{-/-} epicardial cells have altered expression of ECM associated genes

GO and GRN analysis of genes whose expression was >2-fold dysregulated between *Tgfr3*^{+/+} and *Tgfr3*^{-/-} cells for each ligand incubation group revealed biological processes associated with ECM production, ECM binding, cell adhesion, and invasion. The dysregulation of gene expression associated with these processes is consistent with the known defects identified after loss of *Tgfr3* *in vivo* and *in vitro*. Epicardial cell abnormalities in *Tgfr3*^{-/-} embryos include expansion of the subepicardial space and a hyperplastic, irregular epicardium, both of which suggest defects in epicardial cell interactions with the ECM [15]. Invasion of epicardial cells is also defective *in vivo* and *in vitro* in cells lacking TGF β R3 [16]. Consistent with a defect in cell interaction with the ECM, we observe that epicardial cells *in vitro* fail to invade in response to high molecular weight HA [16, 64], a major ECM component of the subepicardial space [65]. CD44 is the cell surface receptor which binds HA and this interaction is important for epicardial invasion [44]. Upregulated expression of the chondroitin sulfotransferase, *Chst7*, is associated with increased chondroitin sulfation of CD44 and decreased CD44-HA binding in multiple cell types [59, 66, 67]. *Chst7* had markedly increased expression (>4-fold) in *Tgfr3*^{-/-} cells when compared to *Tgfr3*^{+/+} cells across all ligand incubation groups. These data suggest that the inability of *Tgfr3*^{-/-} cells to undergo invasion in response to HA may result from increased chondroitin sulfation of CD44.

The myocardium and proepicardium both contribute to the ECM contained in the subepicardial space [65, 68], yet the exact makeup and source is unknown. *Tgfr3*^{-/-} epicardial cells show dysregulated expression of genes encoding proteins found in the ECM, suggesting that epicardial contributions to the ECM are altered after loss of TGF β R3. *Mgp*, *Eln*, and *Tnc* have decreased expression in *Tgfr3*^{-/-} cells when compared to *Tgfr3*^{+/+} cells, while *Matn4* and *Emilin1* have increased expression irrespective of ligand. Alterations in the expression of specific

genes were also found to be ligand-specific. *Versican* is an ECM component contained in the sup epicardial space [69] that promotes cell invasion in some cancer cells (reviewed [70]) and is required for endocardial cushion formation and subsequent EMT [71, 72]. *Versican* has >2-fold higher expression after ligand (TGF β 1, TGF β 2, BMP2) incubation when compared to VEH in *Tgfb3*^{+/+} cells. Ligand induction of *Versican* expression is decreased in *Tgfb3*^{-/-} cells (S3 Fig), demonstrating that *Versican* expression is dependent on *Tgfb3*-ligand interaction. Together, these data suggest the defects in coronary vessel development are due to both the altered response to, and expression of, ECM components by epicardial cells following the loss of *Tgfb3*.

TGF β - and BMP-mediated gene expression programs are dysregulated in *Tgfb3*^{-/-} epicardial cells

Distinct differences were observed in dysregulated gene expression between epicardial cells incubated with BMP and TGF β ligands after loss of TGF β R3. Analysis of the genes dysregulated between *Tgfb3*^{+/+} and *Tgfb3*^{-/-} epicardial cells revealed potentially different mechanisms between BMP2 and TGF β 1 or TGF β 2 mediated-GRNs that may underlay a defect in cell invasion. BMP2 is important in the specification and maintenance of proepicardial cell identity [73], directed proepicardial cell migration [74], and epicardial cell loss of epithelial character and invasion [25]. GRNs generated from the genes dysregulated between genotypes after BMP2 incubation revealed a grouping of genes encoding PDZ domain-containing proteins that had decreased expression in *Tgfb3*^{-/-} epicardial cells when compared to *Tgfb3*^{+/+} cells (*Amot*, *Cadm1*, *Cnksr3*, *Lin7a*, *Mpp6*). Several of these genes (*Amot* [57, 75, 76], *Cadm1* [77], *Cnksr3* [78], *Lin7a* [56, 79]) have been previously reported to promote cell migration but a role in the epicardium has not been described. These observations are consistent with the known role in BMP2 in directing epicardial migration and the decrease of invasion observed in *Tgfb3*^{-/-} epicardial cells. These data also provide an intriguing set of candidate genes as the PDZ domain of TGF β R3 and a protein that interacts with this domain, GIPC, are required for TGF β R3-mediated invasion *in vitro* [16]. GRNs generated from the genes dysregulated between genotypes after TGF β 1 or TGF β 2 incubation had different features from the BMP2 network. A large grouping of genes whose expression was reduced after loss of TGF β R3 was localized to the extracellular space in the TGF β 1 and TGF β 2 networks. These genes were involved in the production of ECM components (*Eln*), matrix degradation (*Mmp3*, *Elastase*), and ECM organization (*Mfap2*). A different grouping of genes expressed at higher levels after loss of TGF β R3 localized to the cytoplasm were associated with epithelial sheet stability and non-motile cells (*Krt8*, *Krt18*). The GRNs are consistent with a population of cells with dysregulated ECM interaction and reduced motility. In addition, genes in signaling pathways associated with vascular development and angiogenesis were dysregulated between genotypes with TGF β 1 and TGF β 2 but not BMP2 incubation. This finding is particularly interesting as factors secreted by the epicardium after injury to the heart are hypothesized to promote the formation of new vessels in the impacted area [80]. To support proper coronary vessel development signaling events must be tightly regulated in the epicardium *in vivo*. Our data demonstrates TGF β R3 is an important component of the regulatory machinery that integrates TGF β and BMP signaling in epicardial cells.

Loss of TGF β R3 disrupts NF- κ B signaling in embryonic epicardium

TGF β R3 is required for invasion promoted by TGF β 1, TGF β 2 and BMP2, suggesting that a TGF β R3-dependent signaling mechanism that regulates invasion is shared between these ligands. Our data predicts NF- κ B signaling is dysregulated in *Tgfb3*^{-/-} epicardial cells. GRN's

generated from genes >2-fold differentially expressed between *Tgfb β 3*^{+/+} and *Tgfb β 3*^{-/-} epicardial cells across each ligand incubation group (VEH, TGF β 1, TGF β 2, BMP2) identified NF- κ B signaling as a central node. In support of a role for NF- κ B signaling, genes known to be regulated directly or indirectly downstream of NF- κ B were also dysregulated. Incubation of epicardial cells with TGF β 2 or BMP2 increased NF- κ B activity in *Tgfb β 3*^{+/+} but not in *Tgfb β 3*^{-/-} cells, demonstrating that TGF β R3 is required for NF- κ B activity in epicardial cells. Several mechanisms may account for the ability of TGF β R3 to regulate NF- κ B signaling. Previous studies have found that TGF β R3 can suppress NF- κ B signaling via interaction with β -arrestin2 [81]. IL-1 β , an upstream regulator of NF- κ B signaling, can suppress TGF β R3 signaling by binding to TRAF6 which subsequently sequesters TGF β R3 from TGF β R2 [82]. Here, reduced NF- κ B activity may result from a >2-fold reduction in the expression of an important upstream regulator of NF- κ B signaling, *Il-1r* (reviewed [83]), in *Tgfb β 3*^{-/-} cells when compared to *Tgfb β 3*^{+/+} cells. Reduced NF- κ B activity may also result from decreased expression in *Tgfb β 3*^{-/-} cells of Myosin Light Chain Kinase (*Mylk*) as seen in RNA-seq (S1–S4 Tables) and by qRT-PCR (S3 Fig). MYLK has recently been shown to promote activation of NF- κ B signaling [84]. MYLK kinase activity is required for MyD88 and IRAK4 complex formation, which in turn is required to activate NF- κ B downstream of lipopolysaccharide [85, 86], in lung endothelial cells [84]. Given the known roles of *Mylk* in regulating smooth muscle behavior [87], cell migration [88], and a link to coronary artery disease [89], the elucidation of the regulatory interactions between MYLK, TGF β R3, and NF- κ B in epicardial cells may provide key insights into coronary vessel development.

While TGF β R3 signaling has been previously reported to both inhibit [81, 90] and promote [91] NF- κ B signaling, a consistent fact in all of these studies is that a decrease in NF- κ B activity was coincident with decreased invasion. Here we used a small molecule inhibitor and showed that NF- κ B activity was required for epicardial cell invasion. In a recent, separate study [92], we confirmed that invasion is dependent upon NF κ B signaling and that *Tgfb β 3*^{-/-} cells lack both invasion and NF κ B activation. Overexpression of TGF β R3 in *Tgfb β 3*^{-/-} cells rescues ligand-dependent invasion that is sensitive to NF κ B inhibitors. Further, endocardial cell invasion, a TGF β R3-dependent process [93], is decreased by the inhibition of NF κ B activity. These data suggest that NF- κ B is a shared signaling pathway downstream of ligand and that TGF β R3 interaction is required for cell invasion. Therefore, we propose that the disruption of TGF β R3 regulated NF- κ B signaling is a mechanism responsible for the loss of invasion in epicardial cells and ultimately failed coronary vessel development in *Tgfb β 3*^{-/-} embryos.

Supporting Information

S1 Fig. Variability of RNA-seq data sets. The reads for the two biological replicates (n = 1, n = 2) for each group (VEH, TGF β 1, TGF β 2, BMP2) in *Tgfb β 3*^{+/+} (A-D) or *Tgfb β 3*^{-/-} (E-H) were plotted against each other. There was a high degree of agreement in *Tgfb β 3*^{+/+} (A-D) (R>0.87) or *Tgfb β 3*^{-/-} (E-H) (R>0.89) datasets. These comparisons support a high degree of agreement between biological replicates. (TIF)

S2 Fig. Comparison of differential gene expression between biological replicates. Plots mapping the fold (log base 2) difference >2-fold in expression between VEH and ligand incubated groups in *Tgfb β 3*^{+/+} (A) or *Tgfb β 3*^{-/-} (B) in biological replicates (X-axis: n = 1, Y-axis: n = 2) shown. Genes that have agreement, defined as having >2-fold (p<0.001) increased or decreased expression in a specific comparison in both replicates, are mapped to quadrants I (upper right) or III (lower left) of a plot. Genes that show disagreement, defined as having >2-fold (p<0.001) increased expression in a tissue in one replicate and decreased in another

(or vis versa), are mapped to quadrants II (upper left) or IV (lower right). There was a high degree of agreement in *Tgfb3*^{+/+} (A) ($R > 0.85$) or *Tgfb3*^{-/-} (B) ($R > 0.89$) datasets across all comparisons [94]. Variability between biological replicates was determined.
